Statement of Use

Information in this document is to help biologists in the Agency to identify where analytical errors occur so that they can be reduced or eliminated. Data in the tables provide measures of the accuracy of primary data produced in accordance with the standard methods for the River Invertebrate Prediction and Classification System (RIVPACS) and analysed to the level required for the Biological Monitoring Working Party (BMWP)-score system, including General Quality Assessment. Information in this report may be used to determine statistical confidence limits and the statistical significances of differences between biological samples. This includes comparisons of Observed/Expected (O/E) values and quality bands made by the compare module of RIVPACS III+ and the statistical routine CONCLASS used for GQA surveys.

1. INTRODUCTION

The collection of standard macro-invertebrate samples and their analysis to the level required for the Biological Monitoring Working Party (BMWP) system is the most widely used biological technique for evaluating water quality in the Environment Agency (The Agency). Used with the computer model RIVPACS (River Invertebrate Prediction and Classification System), they are the basis for the Agency's biological classification of water quality, which is used for national General Quality Assessment (GQA) river quality surveys as well as operational requirements, such as Catchment Management Plans and Biological Quality Objectives. These samples are also used for assessing pollution and setting priorities for capital investment. Data from these samples are made available to the public. An independent audit of these biological samples is required to ensure that a high and consistent standard of sorting and identification is maintained, to assess the proficiency of the internal laboratory analytical quality control (AQC) inspectors and to demonstrate the quality of the data to its users.

The 2000 GQA Survey of Rivers was undertaken by the Agency in England and Wales, the Scottish Environment Protection Agency (SEPA) in Scotland and the Industrial Research and Technology Unit (IRTU) in Northern Ireland. Each organisation employed standard collection procedures (Environment Agency 1999a) to ensure that the data collected were compatible with RIVPACS, the computer model developed by the Centre for Ecology and Hydrology (CEH). Each Agency laboratory appointed at least one experienced analyst to act as an internal analytical quality control (AQC) inspector. These inspectors re-sorted a random selection of about 10% of the laboratory's samples. In addition, CEH was contracted to undertake an independent, external audit of the quality of the laboratory analysis of the biological samples. This commission was consistent with the audit performed by IFE for the national River Quality Surveys in 1990 and 1995 and for the routine biological monitoring of freshwater sites each year between 1991 and 1994 and again between 1996 and 1999. The audit for the Agency comprised two elements. The AQC Audit provides a measure of the quality of performance of the AQC inspectors. The Primary Audit provides an independent assessment of the quality of the data, since this was not adjusted for errors identified by the other quality assurance procedures.

This report presents the results of the audit of 520 samples that were sorted and identified by the Agency's primary analysts. The results of the AQC Audit, detailing the quality of the Agency's internal AQC inspections of these samples, are reported separately (Gunn *et al.*, 2001).

2. SAMPLE SELECTION

Samples for audit were selected internally by each of the organisations being monitored. The standard method of selection used by the Agency is described in Environment Agency (1999b). Each Agency laboratory randomly selected for audit 20 samples that had been processed twice (once for primary analysis and once for internal AQC inspection). The biologists processing these samples had no prior knowledge of which samples were to be audited. The precise manner of sample selection, which biologists would be monitored and the number of audit samples from each season, were left to the discretion of the organisation, within the limits of the total number of samples that CEH was contracted to audit.

3. SAMPLE PROCESSING

The normal protocol for Agency biologists was to sort their samples, either live or preserved, within the laboratory. Samples were sorted for the families of macro-invertebrates included in the BMWP system and examples of each scoring taxon were removed. The invertebrates were placed in a vial of preservative (70% industrial alcohol) and the taxa present were recorded on a standard data sheet. The vial of animals and the sorted material were then returned to the sample container and preservative added. Samples for internal AQC analysis were sorted in the same manner as the primary analysis. The AQC inspector's task included confirming the identification of the contents of the vial and the correctness of the data sheet. Any additional taxa found at AQC were to be placed in a separate vial without altering the contents of the primary analyst's vial, although this instruction was not always followed.

Each sample available to CEH for audit should have included:

- i) a data sheet containing a list of the BMWP families found in the sample.
- ii) a vial or vials containing representatives from each family.
- iii) the preserved sample.

When these three elements were present, the sequence of operations at CEH was as follows:

- a) The remainder of the sample was sorted, without reference to the data sheet or to the vial of animals, and the BMWP families identified.
- b) The families contained within the vial(s) were identified.
- c) A comparison was made between the listing of families and those found in the sample by the CEH auditor.
- d) A comparison was made between the listing of families and those identified from the vial(s) by the CEH auditor.
- e) "Losses", "gains" and "omissions" from the original listing of families were noted. In the case of "gains", each additional family was identified, where possible, to species level, in order to clarify any specific repetitive errors. Single representatives of a "gained" taxon were noted as such.
- f) For each "loss" or "gain" the CEH auditor selected a code from a list at the foot of the result sheet to indicate the most likely cause of the error.

Definitions

Losses are taxa recorded as present by the analyst whose quality is being audited, but which were not found in the vial or sample by the auditors. Gains are taxa found in the vial or sample by the auditors, which were not recorded as present by the analyst whose quality is being audited. Omissions are taxa which were recorded as present by the analyst whose quality is being audited, and which the auditors find in the sample, but not in the vial.

Occasionally a sample did not include a vial containing representative examples of the families listed on the data sheet, while some arrived with the vial damaged in transit such that the representative specimens were no longer separated. For these samples, only operations a), c), e) and f) above were appropriate.

Several directives were issued to CEH relating to the treatment of BMWP taxa. Every taxon recorded on the data sheet must be supported by a voucher specimen of that family in the vial (or, for very large specimens, left in the sample). The only exceptions to this rule were the native crayfish, *Austropotamobius pallipes*, the medicinal leech, *Hirudo medicinalis* and the pearl mussel, *Margaritifera margaritifera* (which does not belong to a BMWP family), all of which are protected species. Animals deemed to have been dead at the time of sampling, cast insect skins, pupal exuviae and empty mollusc shells were to be excluded from the listing of families present. Isolated posterior ends of "living" specimens were not acceptable as records of a taxon. In these cases, thorax plus abdomen was deemed acceptable but abdomen only was deemed unacceptable. Terrestrial representatives of BMWP scoring

families were also to be excluded from the audit. For this reason, Clambidae, Chrysomelidae and Curculionidae, which appear in the BMWP list, were excluded for the purposes of the audit since most representatives of these families are, at best, only semi-aquatic. Trichopteran pupae, although not routinely identified by many biologists, were to be included in the listing of families.

4. REPORTING

The results of each sample audit were recorded on a standard report form (see Figs 1 & 2) and sent to the Agency's Project Manager and the appropriate Regional Biologist. For audit samples where a vial of animals was included, the comparison between the listing of families and the taxa found in the vial by CEH was shown in the section of the report form headed "VIAL". Discrepancies could be due to carelessness, misidentifications or errors in completing the data sheet listing the families present. Families not on the listing but found by CEH in the remainder of the sample were entered in the section of the report form headed "SAMPLE" under "Additional BMWP taxa found in sample". For Primary Audit results, this section also includes taxa added by the internal AQC analyst. Taxa recorded here represent families missed by the analyst(s) on sorting the sample. When the families listed as "losses" in the first section of the report form were compared with the full list of families recorded in the sample by CEH, some apparent losses from the vial were offset by the presence of those families in the remainder of the sample. These taxa were therefore listed both as "losses" from the vial and as "gains" from the sample and were neither a net loss nor a net gain. In these cases, the families were marked with an asterisk in both boxes to highlight this fact. Such errors are noted as "omissions" and were generally caused by an analyst forgetting to place an example of the taxon in the vial, although occasionally, when an animal in the vial had been mis-identified that taxon was subsequently found in the sample by the CEH auditor.

Species identifications, state of development (eg adult or larval coleopterans) and the presence of a single representative of a family were recorded in the centre section of the report form.

CEH was asked to interpret each error to provide a possible cause. An error code, selected from a list of options at the foot of each result sheet, was entered against each taxon in the column headed "Presumed cause of error". Where an error was modified by the findings of the internal AQC inspector, a code to indicate this was selected instead (either code 11 or 12).

For those samples in which the vial of animals was damaged or missing, the "VIAL" sections of the report form were not applicable (N/a). Families not on the list but present in the sample were entered in the section under "SAMPLE" and "Additional BMWP taxa found in sample", as before. Families recorded on the list but not found by CEH were indicated in the section headed "BMWP taxa not found in sample." If the vial of animals had been retained by the sorter, entries in this box could include the sole representative of a family which was removed, a family seen at the site which escaped or was released (without mention being made on the data sheet), inaccurate identification or the wrong family box being ticked on the data sheet.

The final section of the result sheet summarises the audit, giving details of the numbers of "losses", "gains" and "omissions", together with the net effects on BMWP score and the number of scoring taxa.

- 10 Unexplained error
- 11 Taxon added in internal AQC
- 12 Recorded taxon that was rejected by AQC analyst

Omission (*) = Recorded, not in vial but found by CEH in sample (no net loss or gain)

5. RESULTS

The results of the Primary Audit for 2000 for the Agency are presented, region by region, in Tables 1 to 58. A summary of the basic audit results in terms of losses, gains and omissions is followed by the statistics of these regional audit results centered on the target of acceptability of no more than two missed taxa per sample. These data are presented for each analyst, for their area laboratories and for the region as a whole. Then follows information on the net effects of the Primary Audit on the BMWP score and number of scoring taxa. Following this are listings for the region of the taxa missed at family and species levels in the 2000 Primary Audit. Tables 59 and 60 summarise the statistics and net effects of the 2000 Primary Audit for the whole of the Agency. Tables 61 and 62 give listings of all taxa, at family and species levels respectively, missed in sorting by the Agency's primary analysts. Tables 63 and 64 give similar listings of taxa missed 5 times or more for the entire 2000 audit for the whole of the UK. Data for the AQC Audit are presented in a separate report (Gunn *et al.*, 2001).

Estimating sample biases for the compare module of RIVPACS III+

The underestimation of the number of BMWP-scoring taxa is termed bias for the purpose of the compare module of RIVPACS III+. An estimate of bias is provided by the net gains (number of gains minus number of losses). The average net gains for each laboratory, Region and the Agency as a whole are listed in Table 60 in the column "mean net effect on no. of taxa". These values may be used directly for RIVPACS. To estimate the bias over a different period to that covered by this audit, it is necessary to refer to the Primary Audit result sheets for individual samples. Note that estimates of bias should be based on the results of at least 20 audited samples. Further instructions are given in Clarke *et al.* (1997).

6. ACKNOWLEDGEMENTS

Grateful thanks to the Agency's project leader, John Murray-Bligh of Thames Region, who provided invaluable assistance in the development of the audit methodology and who has been a reliable source of helpful advice throughout the period of the audit
