## IMPACT ASSESSMENT OF A SCOUR VALVE TEST AT ROADFORD RESERVOIR ON WATER QUALITY OF THE RIVER LYD.

### SUMMARY

South West Water Services Ltd. released water from Roadford Reservoir on 21 October 1991 to test the operation of the scour valves for dam safety purposes. Flow at Lifton Bridge increased from 2.6 cumecs to a maximum flow of 8.5 cumecs over a period of 3 hours.

Hourly samples were collected at Lifton Bridge on the River Lyd to assess the impact of the release on water quality. Suspended solids and particulate metal concentrations were found to increase as river flow increased. Relevant Environmental Quality Standards for concentrations of total zinc, total iron and suspended solids were exceeded at peak flow. The cause was considered to be the re-suspension of solids from the river bed.

The solids may have been recently deposited during reservoir operation. Alternatively the source of metalliferous solids could be a legacy of the reservoir construction when there was disturbance of mineralised deposits and soils.

Although there was exceedance of EQS's during the dam safety test, the impact on river uses, such as the protection of salmonid fish, is considered to be negligible. This is because the event was short lived.

In addition, the EQS failure for zinc was marginal. High suspended solids concentrations also occurred naturally in the River Lyd prior to the construction of Roadford Reservoir.

It is recommended that geochemical surveys of river sediments are carried out and compared to previous surveys to determine any changes in sediment quality. South West Water Services Ltd. should be notified that future scour valve tests at Roadford Reservoir should be carried out during naturally high river flows in order to ensure any re-suspended solids are flushed from the system and are effectively diluted. This action plan should be developed by SWW in cooperation with the NRA and Riparian Owners and subject to flood defence requirements.

## IMPACT ASSESSMENT OF A SCOUR VALVE TEST AT ROADFORD RESERVOIR ON WATER QUALITY OF THE RIVER LYD.

### 1. INTRODUCTION

As part of the safe operation of reservoirs, scour valves are installed at the base of dam walls to ensure that rapid draw-down of water in the reservoir can occur during emergencies. Reservoir operators are required to have these scour valves inspected regularly by civil engineers. Part of the inspection may require the scour valves to be opened fully to make sure they are not blocked and to ensure that they function properly.

This report describes the impact of a scour valve test at Roadford Reservoir on downstream water quality in the River Lyd at Lifton on 21 October 1991 (see Fig. 1).

The approach of the study was to monitor water quality hourly during the safety test and to compare results with Environmental Quality Standards (EQS's). The monitoring site at Lifton was chosen because it was the site of maximum impact during previous test releases.

### 2. STUDY AREA.

The Rivers Wolf, Thrushel and Lyd have been assigned River Quality Objectives (RQO's) using the National Water Council (NWC) classification of Class 1B. Water quality is routinely monitored at 5 sampling sites (see Fig. 1). Recent classifications are shown in Table 1.

TABLE 1. NWC Classifications (1985 to 1990)

River	Reach upstream of	85	86	87	88	89	90
Wolf	Rexon Bridge	1B	1B	1B	1B	1B	1B
Wolf	Thrushel confluence	1B	2	1B	1B	1B	1B
Thrushel	Tinhay Bridge	1B	1B	1B	1B	1B	1B
Lyd	Lifton Bridge	1B	1B	1B	1B	1B	1B

Routine chemical monitoring started at Newbridge immediately downstream of Roadford Reservoir on 8 October 1991 and as such there is insufficient data for the NWC Classification.

Aquatic invertebrates are sampled at 5 sites (see Fig. 1). During 1990 the river stretch downstream of Roadford Reservoir to Lifton was classified as Class A.

The National Rivers Authority South West (NRA SW) have continued to use the following use-related Environmental Quality Objectives for the Rivers Wolf, Thrushel and Lyd:

- \* Protection of Aesthetic Quality
- \* Protection of Direct Abstraction for Potable Supply
- \* Protection of Salmonid Fish
- \* Protection of Other Aquatic Life/Dependant Organisms

- \* Protection of Livestock Watering
- \* Protection of Irrigation of Crops

The River Wolf prior to the confluence with the River Thrushel down to Lifton Bridge has been designated for the protection of salmonid fish under the EC Freshwater Fish Directive (see Fig. 1 for sampling sites). All sites complied with the EC Freshwater Fish Directive during 1990.

### 3. METHODS.

Hourly samples were collected at Lifton between 11:00 hrs on 21 October 1991 and 02:00 hrs on 22 October 1991, and analysed for suspended solids, dissolved metals and total metals.

River water quality was recorded at Lifton and Newbridge using continuous water quality monitors. The fixed site monitor at Lifton proved unreliable and was therefore replaced with a portable PHOX 100 DPM monitor. Parameters recorded included dissolved oxygen, temperature, pH, conductivity and turbidity (not at Lifton) every 15 minutes. River flow data was collected from the gauging station at Lifton and Newbridge.

### 4. RESULTS.

During the test release the flow at Lifton increased from 2.6 cumecs at 13:00 hrs to a peak of 8.5 cumecs at 16:00 hrs (Fig. 2). Maximum flow was higher than the average daily flow (ADF = 4.56 cumecs for 1991).

At peak flow, suspended solid concentrations, total iron and total zinc concentrations exceeded relevant EQS's (see Table 3 and Fig. 2).

Table 3. Exceedence (\*) of the EQS at Lifton.

22-Oct-91	01:00	6.9	0.50	0.009
	02:00	5.5	0.42	0.006

Dissolved metals, dissolved oxygen, temperature and pH complied with EQS's at Newbridge and Lifton sites (see Appendix I).

## 5. DISCUSSION.

The discharge of water during the safety test at Roadford Reservoir had an impact on water quality by increasing concentrations of suspended solids in the River Lyd at Lifton. High concentrations of particulate metals were associated with the suspended solids. Dissolved metals concentrations did not change significantly because the pH remained neutral.

Although there was exceedance of EQS's during the scour valve test the impact on river uses such as the protection of salmonid fish, is considered negligible. This is because the duration of the event was short (approximately 2 hours). In addition, EQS failure for total zinc concentrations was marginal. High suspended solids concentrations (up to 315 mg/l) have also been recorded at Lifton Bridge prior to the construction of Roadford Reservoir (see Appendix II).

It must be noted that the river hardness during this study was just within the 0-50 mg/l hardness band which gives rise to a strict standard (= 0.030 mg/l). If an annual average hardness value had been used then the 50-100 mg/l hardness band would have been used resulting in a more relaxed standard for total zinc (=0.200 mg/l).

Previous work at Roadford Reservoir in 1990 during a scour valve test also demonstrated an increase in suspended solids and metal concentrations at Lifton. Flow from the reservoir was gradually increased from the compensation flow ( $\approx$ 0.1 cumecs) to a maximum flow of 7.6 cumecs over a period of 5 hours. During this test concentrations of suspended solids and particulate metals increased downstream of Roadford Reservoir (Ref. 1)(see Appendix III).

### 5.1. Sources of suspended solids and particulate metals.

The 1990 study did not detect an impact on water quality at Newbridge immediately downstream of Roadford Reservoir (see Appendix III). It is therefore assumed that the source of suspended solids and metals is from re-suspended particles from the river bed and erosion of river banks during the high flow event. The source is therefore not considered to be from bottom sediments in the reservoir.

The presence of metalliferous solids on the river bed could be a legacy of reservoir construction and basin clearance during 1988. Land disturbance resulted in an increase in quantity of fine material in river gravels for up to 5 km below the dam site (Ref 2). Disturbance of mineralized areas also resulted in higher concentrations of zinc in river sediments downstream of the dam (Ref. 3). However, a reduction in the quantity of fine material in river gravels has occurred after one year of operation of Roadford Reservoir (Ref. 4).

Metalliferous sediments can accumulate downstream of reservoirs. When low dissolved oxygen occurs during reservoir stratification, metals are brought into solution. These are then precipitated on the downstream river bed under

highly oxygenated conditions if a discharge is made from the bottom water. It is not known whether the destratification techniques used at Roadford Reservoir prevent solution of very low concentrations of metals. If low concentrations of metals are released from the reservoir these may gradually accumulate in the river bed.

### 5.2. Remedial measures.

A protocol should be developed to regulate future scour valve releases. This should ensure scour valve testing safety testing at Roadford Reservoir is carried at a time of naturally high river flows in the catchment when metals and suspended solids concentrations are effectively diluted, and that they are flushed from the river system.

### 6. CONCLUSIONS.

1. Suspended solids, total iron and total zinc concentrations exceeded relevant EQS's for approximately 2 hours during a scour valve test on 21 October 1991.
2. The impact on river users was considered to be negligible.

### 7. RECOMMENDATIONS.

1. A repeat geochemical survey of river sediments should be carried out to determine whether there is a change in sediment quality.

Action - Freshwater Officer

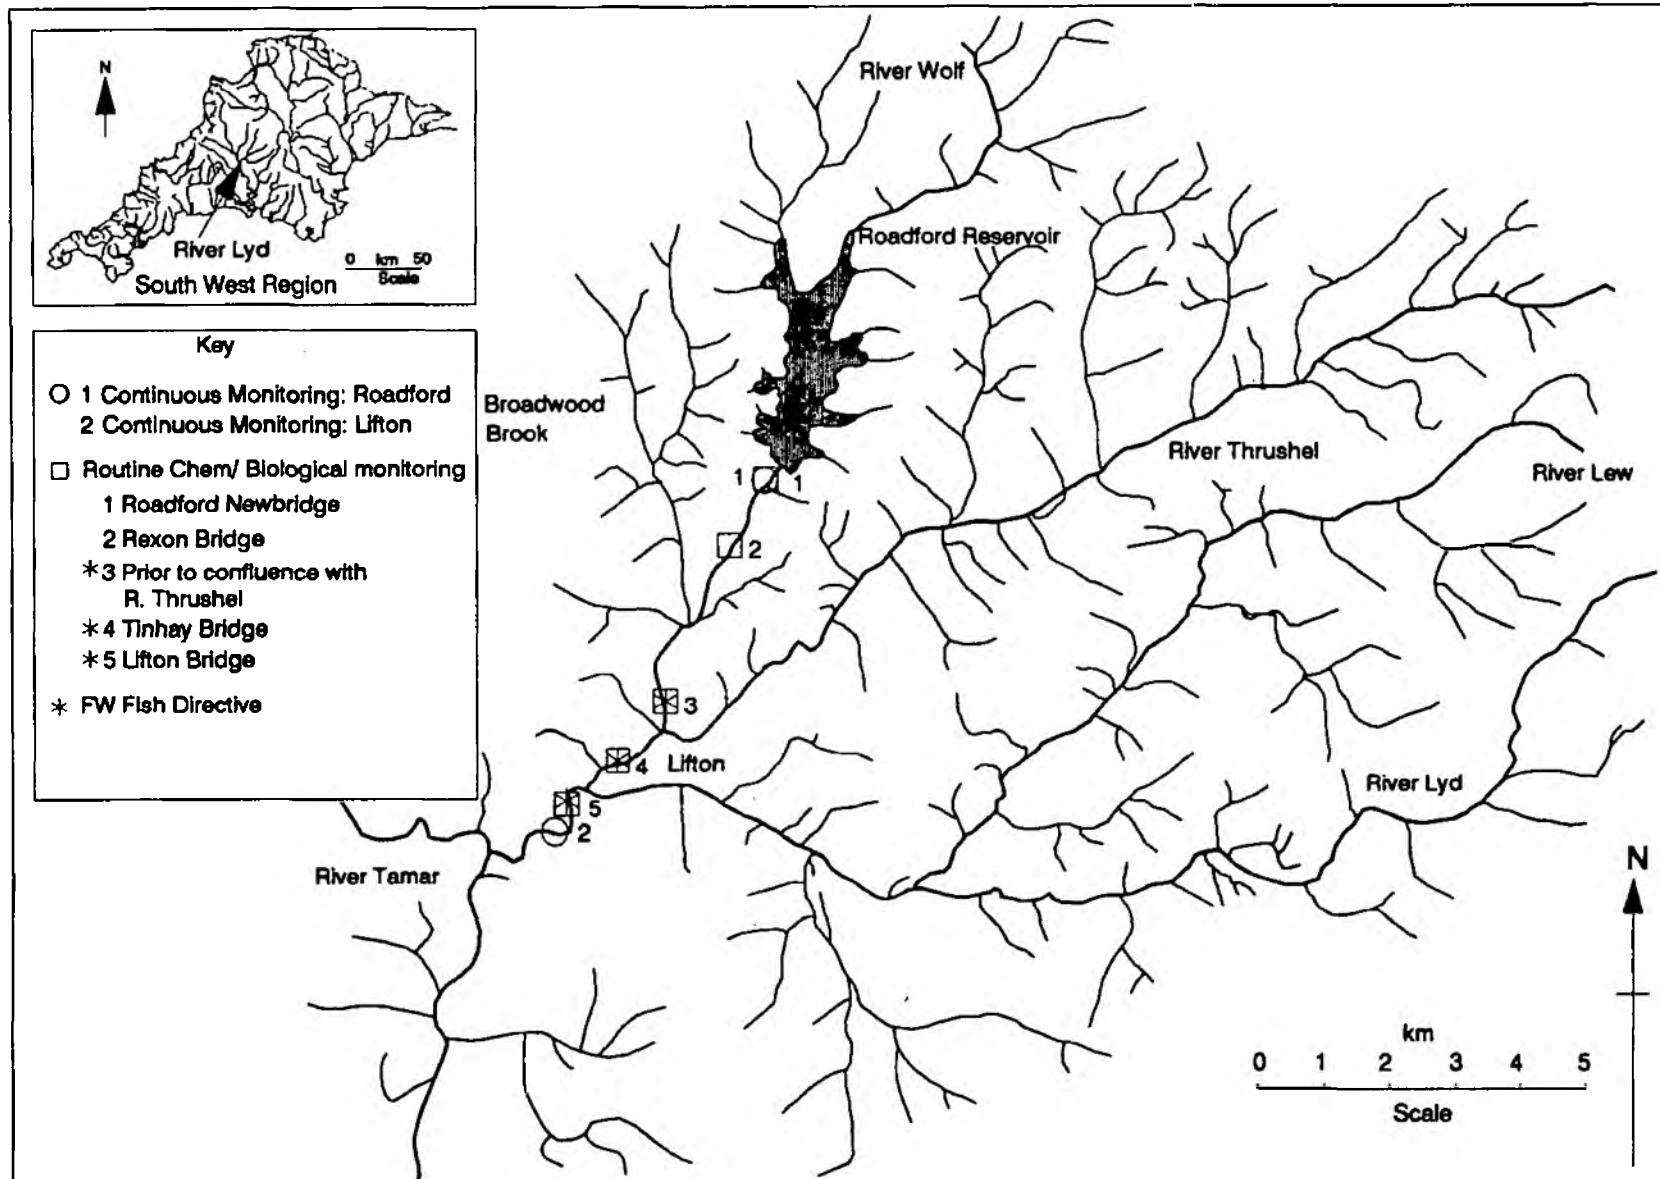

2. South West Water Services Ltd should be informed that the scour valve test at Roadford Reservoir should be carried out during naturally high river flows according to a protocol in cooperation with the NRA and Riparian Owners and subject to flood defence requirements.

Action - Freshwater Officer / Quality Regulation Officer / Pollution Officer

**Appendix III.** Total and dissolved metals concentrations and suspended solids concentrations collected at Lifton and Newbridge during a scour valve test at Roadford Reservoir during November 1990.

Total metals, suspended solids concentrations and flow data collected at  
Litton Bridge during 8 November 1990.

EQS's from the EC Freshwater Fish and Dangerous Substances Directive.  
EQS given as 95 % ile (= 4 X annual mean standards).

**Total metals, suspended solids concentrations and flow data collected at Roadford during 8 November 1990.**
