WOOLACOMBE BEACH - TRACER SURVEY

1. INTRODUCTION

Woolacombe beach is situated in North Devon, and has a major importance to the region as a popular beach for both surfers and tourists. The beach is approximately 3.2 Km long and is sampled at two sites, Woolacombe (village) at the north end and Woolacombe (Putsborough) at the south end of the beach.

At the north end of the beach there is a sewage outfall discharging treated effluent from Woolacombe STW. Swimming, surfing and diving also takes place in the vicinity of the outfall which lies outside the specified area of the Designated Bathing Water.

In 1995, Woolacombe (Putsborough) failed the EC Bathing Waters Directive and Woolacombe (village) passed this directive but did not achieve its European Blue flag award. This award takes into account the EC bathing waters guideline (G) levels which are set lower than the mandatory levels (imperative "I" values).

2. TERMS OF REFERENCE

2.1 OBJECTIVES

A request was received from Devon Area Survey Officer to determine if the discharge from Woolacombe STW, comes onto Woolacombe beach in a tidal cycle during light north - westerly winds..

2.3 PROJECT TEAM

T Cronin (Project Leader)

A Loxton (Project Manager, Author)

3. METHOD

1. Continuous injection of *B. Globigii* (biological tracer) into Woolacombe STW outfall. The injection site is located at the pumping station just to the north of Woolacombe (village) beach (Figure 1). The discharge is gravity fed and the pumping station is approximately 400m from the end of the pipe. A time of travel study had not been carried out but it was estimated to be 15 minutes.
2. Background samples were taken from the beach and offshore (positions fixed by GPS) before the *B. Globigii* was injected.
3. Nine sampling runs were carried out at 5 beach sites and 15 offshore sites (positions fixed by GPS). All sampling runs started at Putsborough.
4. All samples were analysed for *B. Globigii* and salinity.

5. A spring and a neap tide survey were undertaken.

4. RESULTS

4.1 HISTORIC RESULTS

All the data for the routine bathing water samples for Woolacombe (village) and Woolacombe (Putsborough) beaches can be seen in Appendix I.

Analysis of the routine data for Woolacombe (Putsborough) beach shows that both total and Faecal coliform levels are usually well below the mandatory levels set by the Bathing Water Directive, except on the two occasions in 1995 that caused it to fail the Directive. The results from the 1996 bathing water samples (up to 10/09/96), show that the total and Faecal coliform and Faecal streptococci levels have been consistently very low. All samples not only being well below the mandatory levels but also below the guideline levels set by the EC. At present there is no mandatory level set for Faecal streptococci.

Analysis of the routine data for Woolacombe (village) beach, shows that total and faecal coliform levels are usually below the mandatory levels set by the Directive except on one occasion in 1995. This one exceedance of the mandatory level together with exceedances in the guideline level for Faecal streptococci resulted in its failure to retain its Blue flag. The results from the 1996 bathing water samples (up to 10/09/96), show that although the levels for total and Faecal coliform are below the mandatory levels they are close to the guideline levels.

4.2 INVESTIGATION RESULTS

SPRING TIDE TRACER SURVEY - 18/07/96

The results for the background run and the nine sampling runs for the spring tide survey are shown in Appendix II. For each sampling run, the *B. Globigii* result has been plotted next to the sampling position (Appendix II).

The wind direction and speed during the day are shown in Table 1 (Appendix III). The *B. Globigii* titre values and injection rate are shown in Tables 2 and 3 respectively (Appendix III).

NEAP TIDE TRACER SURVEY - 22/08/96

During the neap tide survey, beach samples only were taken, the boat sampling was cancelled due to a severe weather forecast and strong wind warning.

The background results from the neap tide survey are high (Appendix IV). The results from this neap tide survey can not be treated as accurate because of the high background levels recorded on the day. The cause of these high levels is unknown. The only survey that had used *B. Globigii* in the area prior to our survey was at Ashford STW on the 9th August 1996.

Plots showing the sampling positions and corresponding B. Globigii result are shown in Appendix IV.

The wind direction and speed during the day are shown in Table 1, the B. Globigii titre values and injection rate are shown in Tables 2 and 3 respectively (Appendix V).

5. DISCUSSION

The results for the spring tide survey show that B. Globigii was found at Woolacombe (village) beach (site 5), and offshore of this location, from run 8 (High Water -2hrs).

These B. Globigii values can be related to the Faecal coliform no. /100ml by making several assumptions about the quality of the effluent and its flow rate to determine if the levels recorded could result in an exceedance of the mandatory level for Faecal coliforms. These assumptions are detailed below and they are used by the Environment Agency in the assessment of new schemes.

Woolacombe STW is a secondary treated works, assume that the number of Faecal coliform for Woolacombe STW is $3.0 * 10^5$ /100ml.

The consented dry weather flow for Woolacombe STW is 27.78 ltr/sec

Therefore, the Faecal coliform loading rate for Woolacombe STW is $8.3 * 10^7$ ltr/sec

Spring tide survey - Average B. Globigii titre value is $1.18 * 10^{10}$ /100ml

- Assume B. Globigii injection rate to be 1 ltr/hr
(This assumption was made because B. Globigii was not found at the outfall location until 1035 (GMT), and from this time the flow was on average 1 ltr/hr).

Given the above assumption for the injection rate the B. Globigii loading rate is $3.28 * 10^7$ ltr/sec

Therefore, given the above assumptions the ratio of Faecal coliform to B. Globigii during the spring tide survey is 2.5 : 1

If the B. Globigii levels recorded at site 5 are multiplied by this ratio the levels are still below the mandatory levels ("I" values) for Faecal coliforms but they are near and do exceed the guideline (G) values for Faecal coliforms (Appendix VI).

No B. Globigii was found at the south end (Putsborough) of Woolacombe Beach.

During the spring tide survey the winds were generally light all day but offshore.

The effluent flow was generally at a consistent level during the spring tide survey, with a doubling of this level in the morning from 0800 to 1000 (GMT).

The discharge from the works is usually continuous. There is the ability to use the pumping station as a storage tank when problems are experienced at the works or increases in flow are expected with the resulting stored effluent being released gradually. During the neap tide survey this storage facility was in operation because of the expected flow increase as a result of the Radio 1 Roadshow being at Woolacombe on the previous day. The effluent flow during the neap tide survey was at least three times the maximum flow during the spring tide survey. It is unfortunate that the neap tide survey results can not be used because the flow during the day was probably nearer to its maximum daily flow rate consent (152.13 ltr/sec).

Both dogs and horses have been seen on the beach and it is possible that the exceedances in the mandatory levels were the result of animal faeces on the beach especially as the samples with the high levels of Total and Faecal coliform had a high value for Faecal streptococci. Also, dog faeces were photographed on the beach during the neap tide survey (photographs 1 and 2).

A bacteriological study of the Woolacombe stream and its impact on the beach was carried out in April and August 1996 (Report No. DEV/E/18/96).

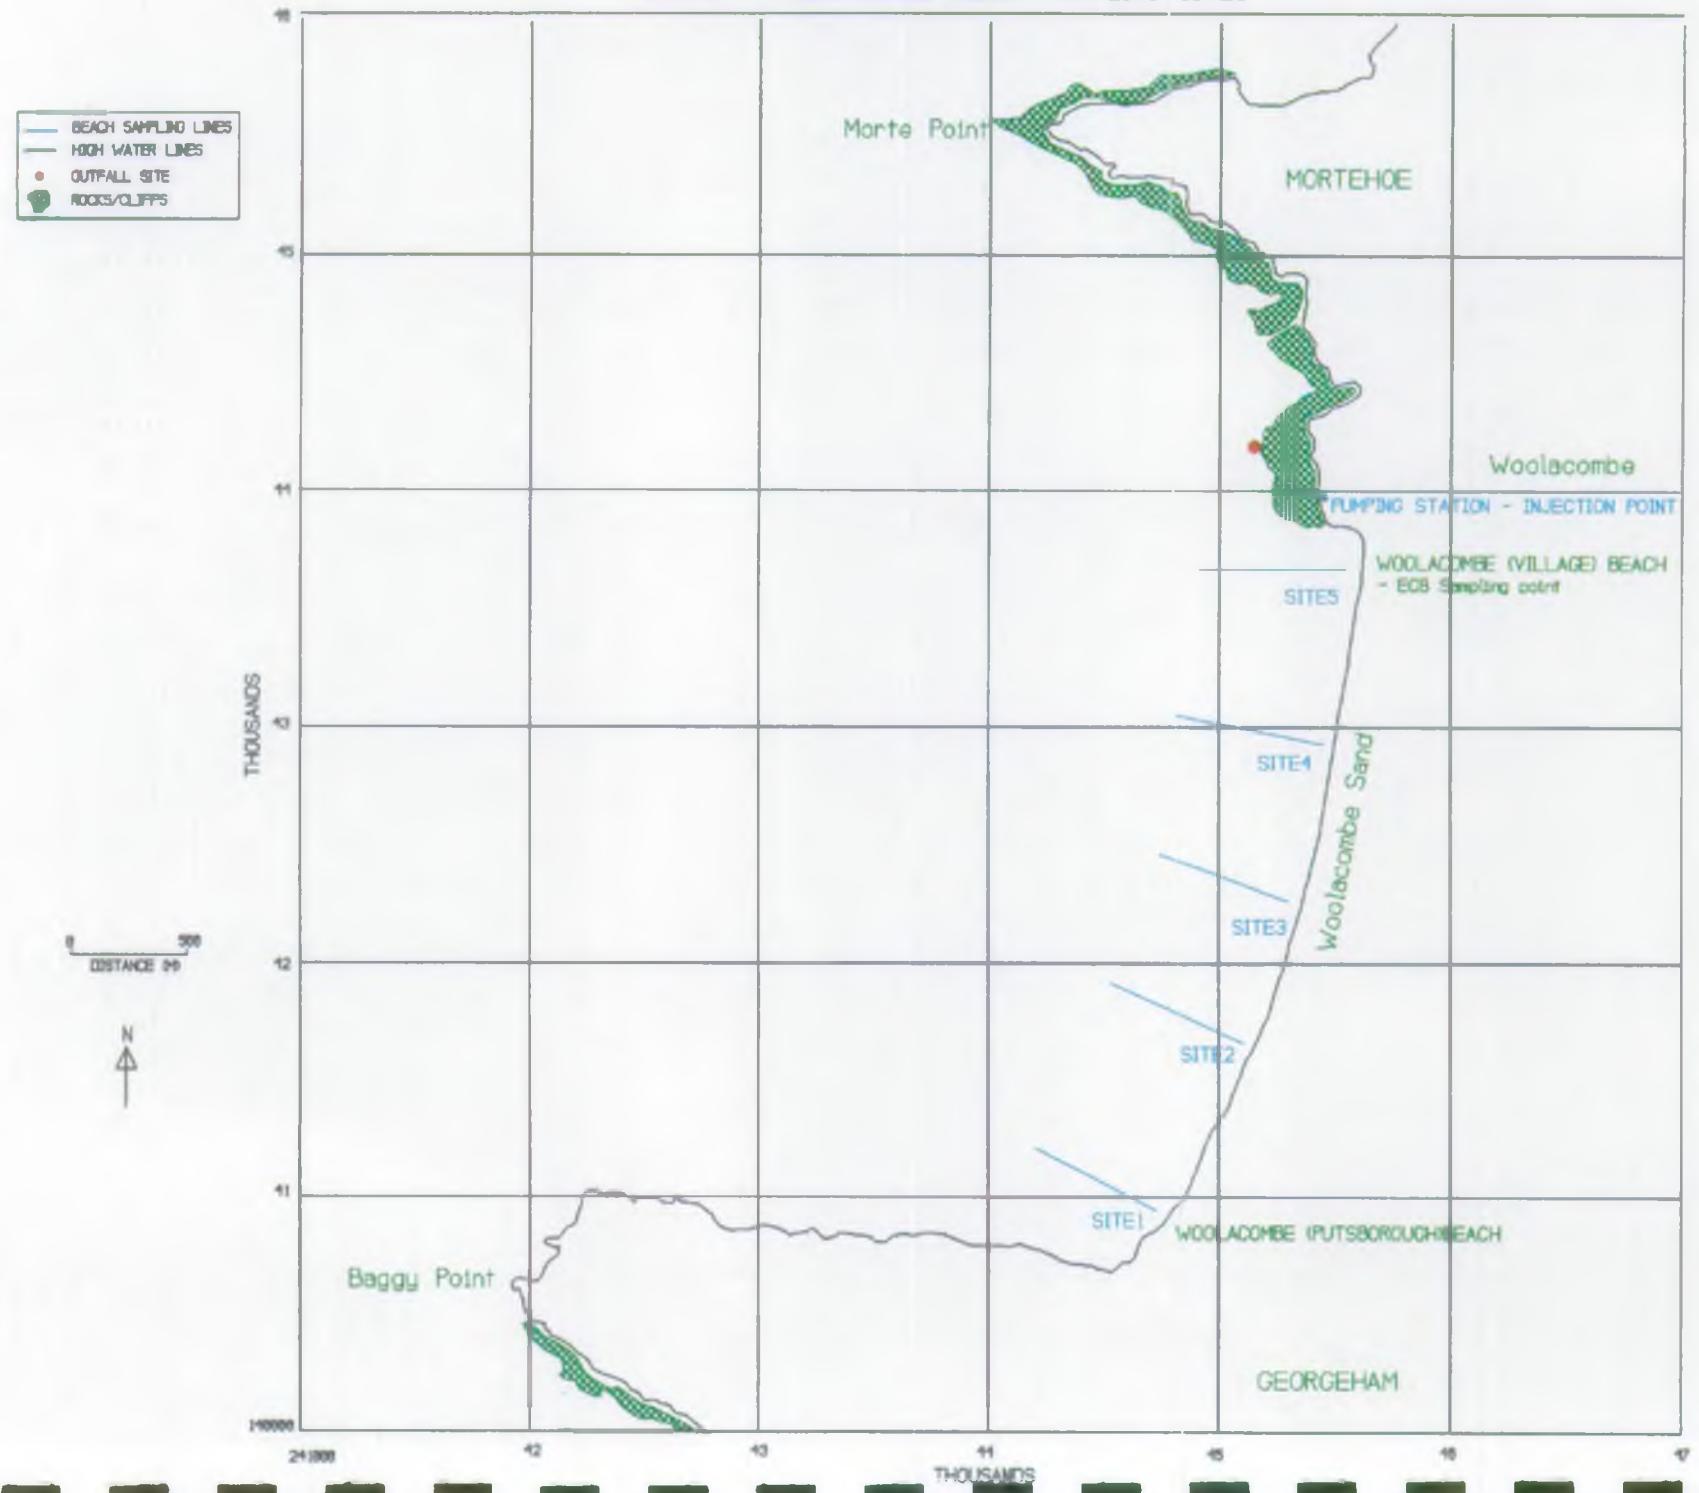

6. CONCLUSION

1. B. Globigii was found on the beach on three successive runs which when "converted" were below the "I" values for Faecal coliforms.
2. Elevated levels of B. Globigii were, as expected, found around the outfall.
3. B. Globigii was found at a number of offshore locations which when "converted" were above the "I" values for Faecal coliforms.
4. There is not enough evidence to say that Woolacombe STW was not and could not be the cause of the high bacteria levels recorded at either Woolacombe (village) or Woolacombe (Putsborough) beaches.

7. RECOMMENDATIONS

1. Repeat of both the spring and neap tide surveys during onshore winds (north-westerly).
2. Use of dye and / or drogues to determine the tidal currents in the area. The nearest tidal information is for Morte point where there is a tidal race.
3. The owners of the beach (Parkin Estates and Mr Tucker) enforce the dog ban and perhaps extend it to cover horses.
4. SWWS Ltd to consider implications of swimmers, surfers and divers using the waters for recreational purposes in the vicinity of the outfall.

Appendix VI

EC BATHING WATERS DIRECTIVE

Compliance is generally assessed against the imperative (I) standards for the principal bacteriological parameters total and faecal coliforms. These standards are:

Total coliforms: Max 10,000 per 100ml

Faecal coliforms: Max 2,000 per 100 ml

Bathing waters are allowed a five per cent failure rate in any one year. This means that 19 samples in 20 have to meet the imperative standards for compliance to be achieved.

The principal guidelines (G) standards, which have to be achieved in 80 percent of samples (i.e. 16/20 samples are:

Total coliforms: Max 500 per 100ml

Faecal coliforms: Max 100 per 100ml

Faecal streps.: Max 100 per 100ml (achieved in 90% of samples)
